

# Copying lists and dictionaries

1

This video will discuss how to copy lists and dictionaries.

## Copying lists / dictionaries

- It is occasionally useful to copy a list or a dictionary
- Assigning a new variable does not create a copy, it just assigns another variable to the same list or dictionary.

```
>>> List1 = [1,2,3,4]
```

```
>>> List2 = List1
```

```
>>> del List2[0]
```

```
>>> List1
```

```
[2,3,4]
```

modifying List2 also  
modifies List1 –  
List1 and List2 refer  
to the same list

2

Copying lists or dictionaries can occasionally be useful; however, the correct method for copying a list is not particularly obvious. For example, assigning a new variable to an existing list does not copy the list – the new variable just refers to the original list.

In this example, both the List1 and List2 variable refer to the same list. Modifying List2 also modifies List1.

## Copying lists / dictionaries – “superficial” copy

- To copy a list or dictionary that has 1-level (i.e. contains no sub-lists or sub-dictionaries)...

```
>>> import copy
>>> List1 = [1,2,3,4]
>>> List2 = copy.copy(List1)
>>> del List2[0]
>>> List1
[1,2,3,4]
```

modifying List2  
does not affect  
List1 – List2 is an  
independent list

- Note: this method is not suitable for a list that contains sublists or a dictionary that contains nested lists or dictionaries.

3

The copy module can be used to create a superficial copy of a list or a dictionary. This method will only create a true copy for a 1-level list.

In the example, the copy method creates a true copy of List1. Modifying List2 does not affect List1.

If a list or dictionary contains multiple levels, then the sub-lists and sub-dictionaries will not be true copies – modifying the “copies” will also modify the originals.

## Copying lists / dictionaries – “deep” copy

- To copy a list or dictionaries that has 1 or more levels (i.e. contains sub-lists or sub-dictionaries)...

```
>>> import copy
>>> List1 = [[1,2], [6,7]]
>>> List2 = copy.deepcopy(List1)
>>> del List2[0][-1]
>>> List1
[[1,2], [6, 7]]
```

modifying sublist of  
List2 does not affect  
List1 – List2 and all  
sublists are  
independent of List1

4

The **deepcopy** method will create a true copy for a multi-level list or dictionary.

In this example, all elements of List1 and List2 are independent – modifying a sub-list in List2 does not affect the sub-list in List1.

## Example script – copying list

- Suppose we want to pair each value in a list with every other value in the list but we don't want duplicate pairings...

```
import copy
sppLst = ['FRAM', 'CAOV', 'QURU', 'QUAL', 'ACRU']
sppLst_copy = copy.copy(sppLst)
for spp1 in sppLst:
    del sppLst_copy[sppLst_copy.index(spp1)]
    for spp2 in sppLst_copy:
        print spp1, spp2
```

```
FRAM CAOV
FRAM QURU
FRAM QUAL
FRAM ACRU
CAOV QURU
CAOV QUAL
CAOV ACRU
QURU QUAL
QURU ACRU
QUAL ACRU
```

delete spp1 item  
from the copy list so  
that it will not be in  
any future pairs

5

This slide will show an example of a script that uses a copied list. In this example, we want to pair each item in the list with every other item but we don't want to allow any duplicate pairings.

The list is a single level list so we'll use the **copy** method to copy it.

We'll create a 2-level for loop – the top-level iterates through the original list.

At the beginning of the top-level loop we'll delete spp1 from the copied list. This eliminates redundant pairings.

The 2<sup>nd</sup> level of the loop iterates through the copy of the list.

The result of the script has all possible unique combinations of the list items.
